Structurally, polyatomic ions are similar to the ionic solids we saw earlier. An example of a simple ionic compound, NaCl, is seen below, alongside a more complex ionic solid, AgClO<sub>3</sub>. Notice how both are tightly packed and form a repeating pattern, which lends both compounds strength and brittleness.

Parentheses are necessary because hydroxide, OH<sup>-</sup>, is a polyatomic ion. It helps to consider polyatomic ions as distinct structural units within ionic compounds – you can't split them apart. The takeaway is this: if an ionic compound contains more than one polyatomic ion of the same type,...

A polyatomic ion has two or more covalently bonded atoms that act as a single ion. The polyatomic ion forms ionic bonds with other ions and acts externally as a unit, just like monatomic ions. The resulting polyatomic ionic compounds can take part in the different types of chemical reactions, dissolving and dissociating in water.

In chemistry, an ionic compound is a chemical compound in which ions are held together by ionic bonds. Usually, the positively charged portion consists of metal cations and the negatively charged portion is an anion or polyatomic ion. Ionic compounds have high melting and boiling points, and they tend to be hard and brittle.

Rules for Naming Ionic Compounds Containing Polyatomic Ions. Polyatomic ions are ions which consist of more than one atom. For example, nitrate ion,  $\text{NO}_3^-$ , contains one nitrogen atom and three oxygen atoms. The atoms in a polyatomic ion are usually covalently bonded to one another, and therefore stay together as a single, charged unit.
